

Fore and hind limbs developed into flippers for swimming

Smooth, streamlined shape to pass easily through the water

A substantial blubber layer lies under the skin acting as insulation allowing the seals to swim indefinitely in cold Antarctic waters

Males compete for underwater territories based around a breathing hole which gives access to females using the same breathing hole

They avoid the "bends" when diving by exhaling first and allowing the lungs and air passages to collapse

Large eyes to help hunting prey under water and frequently under ice where light levels are very low
